Purpose: Spinocerebellar ataxias (SCAs) are progressive neurodegenerative disorders with diverse modes of inheritance. There are several subtypes of SCAs. SCA 8, SCA 12, and SCA 17 are the less common forms of SCAs with limited information available on their epidemiological profiles in Korea. The purpose of this study was to investigate the prevalence of SCA8, SCA12, and SCA17 in Korea.

Materials and Methods: Ninety-six unrelated Korean patients were enrolled and showed normal trinucleotide repeats through polymerase-chain reaction (PCR) for the genes ATXN1, ATXN2, ATXN3, CACNA1A, and ATXN7, which correspond to SCA1, SCA2, SCA3, SCA6, and SCA7, respectively. PCR products from patients were further analyzed by capillary electrophoresis using fluorescence labeled primers for the genes ATXN8OS, PPP2R2B, and TBP, which correspond to SCA8, SCA12, and SCA17.

Results: Three patients had 104, 97, and 75 abnormal expanded repeats in the ATXN8OS gene, the causative gene for SCA8. None of the patients exhibited abnormal repeats in SCA12 and SCA17. Normal trinucleotide repeat ranges of the cohort in this study were estimated to be 17-34 copies (average, 24±4 copies) for SCA8, 7-18 copies (average, 13±3 copies) for SCA12, and 26-43 copies (average, 35±2 copies) for SCA17.

Conclusion: This study demonstrated that SCA8, SCA12, and SCA17 are rare in Korean patients with SCA, and further genetic studies are warranted to enhance the mutation detection rate in the Korean SCA population.

Key words: Spinocerebellar ataxia, Spinocerebellar ataxia 8, Koreans.

Introduction

Spinocerebellar ataxias (SCAs) are hereditary neurodegenerative disorders characterized by progressive ataxia, cerebellar dysarthria, spasticity, extrapyramidal signs, cognitive impairment, and epilepsy [1,2]. SCAs are divided into autosomal dominant, autosomal recessive, X-linked, and mitochondrial SCAs according to the mode of inheritance. Among these, autosomal dominant SCAs is the most common subtype, and more than 30 autosomal dominant SCAs have been identified to date. The causative genes associated with SCAs include SCA1 (ATXN1), SCA2 (ATXN2), SCA3 (ATXN3), SCA5 (SPTBN), SCA6 (CACNA1A), SCA7 (ATXN7), SCA8

(ATXN8OS), SCA10 (ATXN10), SCA11 (ITBK2), SCA12 (PPP2R2B), SCA13 (KCN2), SCA14 (PKC), SCA17 (TBP), SCA19/22 (KCN3), SCA21 (TMEM240), SCA22 (FGF14), SCA28 (AFG3L2), and SCA29 (ITPR1), and recent developments in the genetic field using next-generation sequencing techniques continue to reveal the new causative genes in SCAs [3,4]. SCA1, SCA2, SCA3, SCA6, and SCA7 are the most prevalent forms of SCA worldwide. However, only a few studies have been conducted in the Korean population [5-8]. Among these, SCA2, SCA3, and SCA6 are found to be the most common subtypes, followed by SCA7 and SCA1 [9]. However, in 70% of the patients, their SCA subtypes remain unidentified as routine screenings were only conducted for SCA1, SCA2, SCA3, SCA6, SCA7, and SCA13 [10]. With the exception of a few case reports, the prevalence of SCA8, SCA12, and SCA17 in the Korean population remains relatively unknown [11,12].

This study was performed to investigate the prevalence SCA8, SCA12, and SCA17 in Korean patients with SCAs who were negative for SCA1, SCA2, SCA3, SCA6, and SCA7.

Materials and Methods

This study was approved by the Institutional Review Board of Asan Medical Center, Seoul, Korea. Ninety-six unrelated Korean patients (44 males and 52 females) with clinically suspected SCA who had normal trinucleotide repeat (TNR) copy numbers of SCA1 (ATXN1), SCA2 (ATXN2), SCA3 (ATXN3), SCA6 (CACNA1A), and SCA7 (ATXN7) were enrolled in this study. The mean age at enrollment was 53 ± 10 years.

Genomic DNA was isolated from peripheral blood leukocytes using the Gentra Puregene blood kit (Qiagen, Hilden, Germany). Genes for SCA1, SCA2, SCA3, SCA6, and SCA7 were tested as previously described [9].

To identify abnormal TNR expansion of SCA8 (ATXN8OS), SCA12 (PPP2R2B), and SCA17 (TBP), we used 6-FAM labeled primer sets for PCR, followed by capillary electrophoresis. The primer sequences of SCA8, SCA12, and SCA17 were designed using reference sequences from GenBank NT_024524.14, NT_029289.11, and NT_025741.15, respectively. The primer sequences, 5'-tttgagaaaggcttgtgaggactgagaatg-3' (sense) and 5'-ggtccttcatgttagaaaacctggct-3' (antisense), were used for SCA8, 5'-tgctgggaaagagtcgtg-3' (sense) and 5'-gccagcgcactcaccctc-3' (antisense) for SCA12, and 5'-gaccccacagcctattcaga-3' (sense) and 5'-ttgactgctgaacggctgca-3' (antisense) for SCA17.

PCR was carried out with a final volume of 20 μL, containing 10 ng of template DNA, 1 μM of each primer sets, 200 μM of dNTP mixture, 1.5 mM of MgCl₂, 50 mM of KCl, 10 mM of Tris-HCl (pH 8.3) and 1 unit of Taq polymerase (Promega, Madison, WI, USA). Genes were amplified for 30 cycles with the following parameters: denaturation at 94°C for 30 s, annealing at 55°C for 30 s, and reaction at 72°C for 45 s using the PTC-200 (MJ Research, Watertown, MA, USA). The reaction mixture also contained 0.5 μL of GeneScan500Liz and 10 μL of HiDi formamide (Applied Biosystems) in condition of POP7-polymer. The oven temperature was set at 60°C, injection at 1.2 kV for 20 s, and the gel was run at 15 kV for 1,200 s. Data were analyzed with GeneMapper v4.0 (Applied Biosystems).

Results

Among the 96 patients enrolled in this study, three were heterozygotes for the expanded TNR numbers in the ATXN8OS gene, which is responsible for SCA8 (Fig. 1). None of the patients showed expanded TNR number in the PPP2R2B gene (SCA12) or the TBP gene (SCA17).

1. Clinical and genetic features of three patients with SCA8

1) Case 1

The patient was a 38-year-old female Korean who suffered from dysarthria since the age of 34 years. She also had dysphagia, but no ataxia or gait disturbance. Her mother and grandmother also had gait disturbance. Brain magnetic resonance imaging (MRI) showed prominent cerebellum folia.

Genomic test for the ATXN8OS gene revealed that the patient had 104 (CTG·CAG)n copies (normal range, 5-50 copies) in one allele, with normal numbers (29 copies) of (CTG·CAG)n copies on the other allele.

2) Case 2

A 63-year-old female Korean was presented with ataxia, gait disturbance, dysarthria, and bradykinesia. A brain MRI revealed diffuse atrophy of the pons and the cerebellum (Fig. 2). She had been treated with quetiapine fumarate and fluvoxamine. She had expanded (CTG·CAG)n repeats (97 copies) in one allele of the ATXN8OS gene, while the other allele contained 17 copies of TNRs.

3) Case 3

A 67-year-old female Korean experienced progressive...
gait disturbance since 62 years of age. She had mild rigidity, bradykinesia, and dysmetria. Diminished metabolism in the cerebellum and midbrain was detected via brain positron emission tomography (Fig. 3). She had expanded (CTG · CAG) \( n \) repeats (75 copies) in one allele of the ATXN8OS gene with normal number of TNRs (24 copies) in the other allele.

### 2. Normal ranges of trinucleotide repeats in SCA8, SCA12, and SCA17

The mean copy number of (CUG)\( n \) in the ATXN8OS gene, which was responsible for SCA8, were calculated in 93 patients and were found to be 24±4 repeats (range, 17-34 repeats). Data from the three patients with abnormal number of TNRs were excluded from the analysis. Of note, 17 repeats (29/186 alleles, 16%), 23 repeats (23/186 alleles, 12%), and 26 repeats (26/186 alleles, 14%) were found as the common repeat numbers, comprising 42% of all the alleles tested. The mean copy number of (CAG)\( n \) repeats in the PPP2R2B gene, which was responsible for SCA12, was 13±3 repeats (range, 7-18 repeats) among the 96 patients tested. The mean copy number of (CAG-CAA)\( n \) repeat in the TBP gene, which was responsible for SCA17, was 35±2 repeats (range, 26-34 repeats). We found that 9-15 repeats were common in SCA12, whereas 35 repeats was the most prevalent copy number in SCA17 (Fig. 4).

### Discussion

SCAs are caused by one of the three genetic abnormalities.
The first is the abnormal expansion of a CAG trinucleotide in protein coding regions of specific genes. Out of all SCA subtypes, SCA1, SCA2, SCA3, SCA6, SCA7, SCA12, and SCA17 are caused by abnormal expansion of (CAG)n repeat, which leads to accumulation of toxic poly-glutamine tract. The normal ranges of (CAG)n repeats of SCA1, SCA2, SCA3, SCA6, and SCA7 were 6–39 copies, 14–32 copies, 12–40 copies, 4–18 copies, and 7–18 copies, respectively. The mutant ranges of the TNRs in SCA1, SCA2, SCA3, SCA6, and SCA7 were 41–83 copies, 34–77 copies, 62–88 copies, 22–30 copies, and 38–200 copies, respectively [2].

The second genetic cause of SCA is trinucleotide expansion in the non-coding region like SCA8 and SCA10. The last genetic cause is point mutation in the coding region of morbid genes such as SCA5 (SPTBN), SCA11 (TTBK2), SCA13 (KCNC3), SCA14 (PKC), SCA19/22 (KCND3), SCA23 (PDYN), and more [1].

The common disease manifestation of SCA is progressive neuro-degeneration, but SCA also shows a wide phenotypic spectrum, and its severity is associated with the copy number

size of expanded repetitive nucleotides. Patients with a larger expansion manifest SCA at an earlier age, whereas those with a smaller expansion have late onset-age [4]. In the genetic abnormality of TNR expansions, the expansion size of the TNR is correlated with patient’s prognosis. Thus, it is important to determine the copy numbers of (CAG)n in these causative genes. To date, the relationship between expansion size and disease-onset age of SCA1, SCA2, SCA3, SCA6, and SCA7 have been reported in many studies [9], but, in the case of SCA8, SCA10, SCA12, and SCA17, limited information is available.

Tests for the frequent subtypes, SCA1, SCA2, SCA3, SCA6, and SCA7 are commercially available and are done as a panel tests, whereas tests for the infrequent subtypes, SCA8, SCA10, SCA11, SCA12, SCA13, SCA14, SCA17, SCA27 are usually done individually or as a multi-gene test for the patients who are negative for the frequent subtypes [3]. In our study, the 96 patients enrolled were all negative for SCA1, SCA2, SCA3, SCA6, and SCA7, and the results SCA8, SCA12, and SCA17 tests indicate that these subtypes are very rare, where only three patients were positive for SCA8.

SCA8 is caused by the expansion of (CTA·TAG)n(CTG·CAG)n repeats in 3’-untranslated region of the ATXN8OS gene. Its normal repeat number ranges from 15 to 50 copies, while mutants range from 80 to 250 copies. Recently, SCA8 also known to be caused by (CAG)n repeats in the open reading frame of the ATXN8 gene, an overlapping gene of ATXN8OS. Although the mechanism is not well defined, SCA8 is presumed to occur due to accumulation of toxic RNAs of ATXN8OS like as RNA toxicity by (CTG)n TNR expansion of DMPK in myotonic dystrophy type I [13,14] or due to abnormal polyglutamine expansion of ATXN8 that results from expansion of bidirectional TNRs complementary to the ATXN8 and ATXN8OS genes [15]. Of note, reduced penetrance has been observed even in subjects with mutant-sized allele ranging from 80 to 250 copy numbers.

It should be noted that even subjects with a huge expansion of over 500 copies may not necessarily show ataxia [16]. In this respect, case 3 in the current report had a copy number of 75, which was smaller than the mutant copy numbers, and her cerebellar ataxic manifestation may be explained by high penetrance.

Anticipation is a major issue that should be discussed during genetic counseling with families that have a history of SCA. In case of SCA8, the repeat size is always expanded when it is inherited maternally, whereas it is shortened when paternally inherited [16].

We calculated the normal range of the TNRs in patients who were negative for SCA8, SCA12, and SCA17. The number of TNRs from these patients was within the normal ranges as previously reported, and some common allele sizes were noted in each subtype. The normal copy numbers of SCA8, 12, 17 in Korean population ranged from 17 to 34 (mean 24±4), 7 to 18 (mean 13±3), and 26 to 43 (mean 35±2), respectively. These numbers were similar to previously reported range of 15-50, 4-32, and 25-42 for SCA8, 12, and 17, respectively.

In conclusion, we have identified three SCA8 patients out of 96 unrelated patients with clinically suspected SCA who showed normal TNR copies in SCA1, 2, 3, 6, and 7. There were no patients with SCA12 and 17. Further study should be performed to confirm the prevalence of SCA subtypes as it would provide valuable information to generate gene panel tests for rapid diagnosis of patients who show indications of SCAs in Korea.
