Amlodipine, a dihydropyridine calcium channel blocker, causes coronary and peripheral vasodilatation by blocking the influx of extracellular calcium across cell membranes. Amlodipine is arterioselective and effective for the treatment of hypertension, myocardial ischemia, and vasospasm in surgical patients.  

1) Amlodipine is rapidly absorbed and is extensively metabolized in the liver while it shows linear dose-related pharmacokinetic characteristics and, at steady-state, there are relatively small fluctuations in plasma concentrations across a dosage interval.  

2) Although structurally related to other dihydropyridine derivatives, amlodipine displays significantly different pharmacokinetic characteristics.  

3) Amlodipine is a substrate of cytochrome P450 (CYP) 3A subfamily, specifically CYP3A4. In addition, amlodipine is also a P-glycoprotein (P-gp) substrate.

4) Repaglinide is a new carboxymethyl benzoic acid derivative, also known as 2-ethoxy-4-[2-[[3-methyl-1-[2-(1-piperidinyl) phenyl] butyl] amino]-2-oxoethyl] benzoic acid.  

5) It is a novel post prandial glucose regulator for the treatment of type 2 diabetes mellitus. It reduces fasting glucose concentrations in patients with type 2 diabetes mellitus.  

6) It helps to control blood glucose by increasing the amount of insulin released by the pancreas.  

7) Repaglinide stimulates the release of insulin from the pancreatic β-cell by binding to and closing of ATP-dependent potassium channels. This depolarizes the plasma membrane, leading to the opening of voltage-dependent calcium channels. Influx of calcium ions, which increases intracellular Ca^{2+}, triggers exocytosis.  

8) Key words - Repaglinide, Pharmacokinetics, Amlodipine, CYP3A4, Rat
nosis of insulin.\textsuperscript{12)}

Repaglinide is rapidly absorbed from the gastrointestinal tract after oral administration. It differs from other antidiabetic agents in its structure, binding profile, duration of action and mode of excretion.\textsuperscript{13)} Repaglinide is primarily metabolized via oxidative biotransformation involving the hepatic microsomal cytochrome P450 system, particularly the CYP3A4 isoform.\textsuperscript{14)} The metabolic pathway of repaglinide indicates two major sites for the principal biotransformation of repaglinide: the piperidine ring and the aromatic carboxylic acid group.\textsuperscript{15)} Repaglinide has affinity for P-gp and it can significantly contribute to potential drug-drug interactions with other P-gp substrates or inhibitors.\textsuperscript{16)} Kajosaari et al\textsuperscript{.17)} reported that co-administration of repaglinide with the known P-gp inhibitor cyclosporine A could significantly increase the plasma concentrations of repaglinide in humans.

There are few reports about CYP enzyme and P-gp activity for amlodipine. Therefore, we evaluated the inhibition of CYP enzyme activity and P-gp activity by amlodipine using CYP inhibition assays and rhodamine-123 retention assays in P-gp-overexpressing MCF-7/ADR cells.

Clinically repaglinide and amlodipine can be prescribed for prevention or treatment of cardiovascular disease as complications of diabetes. However, pharmacokinetic interaction between repaglinide and amlodipine has not been reported. Therefore, the present study aims to investigate the effect of amlodipine on CYP3A4 activity, P-gp activity and the pharmacokinetics of repaglinide after oral and intravenous administration in rats.

**MATERIALS AND METHODS**

**Materials**

Repaglinide, amlodipine and indomethacin (internal standard) were purchased from the Sigma-Aldrich Co. (St. Louis, MO, USA). HPLC-grade methanol and acetonitrile were acquired from Merck Co. (Darmstadt, Germany). All other chemicals for this study were of reagent grade and were used without further purification. Apparatus used in this study included an HPLC equipped with a Waters 1515 isocratic HPLC Pump, a Waters 717 plus auto sampler and a Waters 2487 scanning UV detector (Waters Co., Milford, MA, USA), an HPLC column temperature controller (Phenomenex Inc., CA, USA), a Branson Ultrasonic Cleaner (Branson Ultrasonic Co., Danbury, CT, USA), a vortex-mixer (Scientific Industries Co., NY, USA), and a high-speed microcentrifuge (Hitachi Co., Tokyo, Japan).

**Animal experiments**

Male Sprague-Dawley rats (weighing 270-300 g) were purchased from the Dae Han Laboratory Animal Research Co. (Choongbuk, Korea) and were given access to a commercial rat chow diet (No. 322-7-1, Superfeed Co., Gangwon, Korea) and tap water. The animals were housed, two per cage, and maintained at 22±2°C and 50-60% relative humidity under a 12:12 h light-dark cycle. The experiments were initiated after acclimation under these conditions for at least 1 week. The Animal Care Committee of Chosun University (Gwangju, Korea) approved the design and the conduct of this study. The rats were fasted for at least 24 h prior to the experiments and each animal was anaesthetized lightly with ether. The left femoral artery and vein were cannulated using polyethylene tubing (SP45, i.d. 0.58 mm, o.d. 0.96 mm; Natsume Seisakusho Co. LTD., Tokyo, Japan) for blood sampling and i.v. injection, respectively.

**Oral and intravenous administration of repaglinide**

The rats were divided into six groups (n=6, each): an oral control group (0.5 mg/kg of repaglinide dissolved in distilled water, 1.0 ml/kg) without or with 0.1 and 0.4 mg/kg of amlodipine (mixed in distilled water, 3.0 ml/kg), and an i.v. control group (0.2 mg/kg of repaglinide, dissolved in 0.9% NaCl solution, 1.5 ml/kg) without or with 0.1 and 0.4 mg/kg of amlodipine (mixed in distilled water, 3.0 ml/kg). Oral repaglinide was administered intragastrically using a feeding tube, and amlodipine was administered in the same manner 30 min
Effects of Amlodipine on the pharmacokinetics of Repaglinide prior to the oral administration of repaglinide. Repaglinide for i.v. administration was injected through the femoral vein within 0.5 min. A 0.4-ml aliquot of blood was collected into heparinized tubes from the femoral artery at 0.25, 0.5, 0.75, 1, 2, 4, 6, and 10 h after repaglinide oral administration and at 0 (to serve as control), 0.1, 0.25, 0.5, 1, 2, 6, and 10 h after repaglinide i.v. administration. The blood samples were centrifuged at 13,000 rpm for 3 min, and the plasma samples were stored at –40°C until HPLC analysis.

**HPLC assay**

Plasma concentration of repaglinide was determined by HPLC as reported by Ruzilawati et al. \(^\text{12}\) with a slight modification. Briefly, a 50-µl aliquot of 1 µg/ml indomethacin, as an internal standard, and a 0.2-ml aliquot of 0.1 M potassium dihydrogen orthophosphate (KH\(_2\)PO\(_4\), pH 5.9) were mixed with a 0.2-ml aliquot of the plasma sample. After the mixture was vortexed, 1 ml of ethylacetate, 50 µl of isoamylalcohol and 35 µl of 1.0 M NaOH were added. The resulting mixture was then vortex-mixed for 10 min and centrifuged at 9,000 rpm for 10 min. After centrifugation, the ethylacetate phase was transferred into a clean test tube and evaporated under a gentle stream of nitrogen gas at 45°C. The dried extract was reconstituted with 150 µl of mobile phase, vortex-mixed and transferred to a clean autosampler vial. A 70-ml aliquot of the supernatant was injected into the HPLC system. Chromatographic separation was achieved using a µBondapak C\(_{18}\) column (3.9×30 mm i.d., 10 µm, Waters Co.) attached to a µBondapak C\(_{18}\) guard column (3.9×20 mm i.d., 10 µm, Waters Co.). The mobile phase consisted of acetonitrile:0.01 M ammonium formate (pH 2.7, adjusted with phosphoric acid) (56:44, v/v). The flow-rate of the mobile phase was maintained at 1.0 ml/min. Chromatography was performed at 30 and regulated by an HPLC column temperature controller. The UV detector was operated at a wavelength of 244 nm. Repaglinide and indomethacin were eluted with retention times at 7.4 and 8.4 min, respectively. The lower limit of quantification for repaglinide in rat plasma was 20 ng/ml. The intra- and inter-day coefficients of variation of repaglinide were below 12.1 and 11.5%, respectively.

**CYP inhibition assay**

The assays of inhibition of human CYP3A4 enzyme activity were performed in a multiwell plate using CYP inhibition assay kit (GENTEST, Woburn, MA) as described previously. \(^\text{18}\) Briefly, human CYP enzymes were obtained from baculovirus-infected insect cells. CYP substrate (7-BFC) was incubated with or without test compounds in the enzyme/substrate buffer consisting of 1 pmol of P450 enzyme and a NADPH generating system (1.3 mM NADP, 3.54 mM glucose 6-phosphate, 0.4 U/ml glucose 6-phosphate dehydrogenase and 3.3 mM MgCl\(_2\)) in a potassium phosphate buffer (pH 7.4). Reactions were terminated by adding stop solution after 45-min incubation. Metabolite concentrations were measured by spectrofluorometer (Molecular Devices, Sunnyvale, CA) at an excitation wavelength of 409 nm and an emission wavelength of 530 nm. Positive control (1 µM ketoconazole) was run on the same plate and produced 99% inhibition. All experiments were performed in duplicate, and results are expressed as the percent of inhibition.

**Rhodamine-123 retention assay**

The procedures used for the Rho-123 retention assay were similar to a previously reported method. \(^\text{19}\) MCF-7/ADR cells were seeded in 24-well plates and preincubated with amlodipine for 30 min. At 80% confluence, the cells were incubated in FBS-free DMEM for 18 h. The culture medium was changed to Hanks’ balanced salt solution and the cells were incubated at 37°C for 30 min. After incubation of the cells with 20 µM rhodamine-123 in the presence or absence of amlodipine (1, 3 and 10 µM) for 90 min, the medium was completely removed. The cells were then washed three times with ice-cold phosphate buffer (pH 7.0) and lysed in EBC lysis buffer. Rhodamine-123 fluorescence in the cell lysates was measured using excitation and emission wavelengths of 480 and 540 nm, respectively. Fluorescence values were normalized to the total protein con-
Pharmacokinetic analysis

The plasma concentration data were analyzed by the non-compartmental method using WinNonlin software version 4.1 (Pharsight Co., Mountain View, CA, USA). The elimination rate constant ($K_{el}$) was calculated by log-linear regression of repaglinide concentration during the elimination phase. The terminal half-life ($t_{1/2}$) was calculated by $0.693/K_{el}$. The peak plasma concentration ($C_{max}$) and time to reach peak plasma concentration ($T_{max}$) of repaglinide in plasma were obtained by visual inspection of the data from the concentration-time curve. The area under the plasma concentration-time curve from 0 h to the time (AUC$_{0-t}$) of last measured concentration ($C_{last}$) was calculated by the linear trapezoidal rule. The AUC from zero to infinite (AUC$_{0-\infty}$) was obtained by the addition of AUC$_{0-t}$ and the extrapolated area determined by $C_{last}/K_{el}$. Total body clearance (CL/F) was calculated by:

$$CL/F = \frac{Dose}{AUC}$$

The absolute bioavailability (AB) was calculated by:

$$A.B. = \frac{AUC_{oral}}{AUC_{i.v.}} \times \frac{Dose_{i.v.}}{Dose_{oral}} \times 100$$

While the relative bioavailability (RB) was calculated by:

$$R.B. = \frac{AUC_{with\ amlodipine}}{AUC_{control}} \times 100$$

Statistical analysis

Statistical analysis was conducted using one-way ANOVA followed by a posteriori testing with the Dunnett correction. Differences were considered to be significant at $p < 0.05$. All mean values are presented with their standard deviation (Mean±SD).

RESULTS

Inhibition of CYP3A4

The inhibitory effect of amlodipine on CYP3A4 activity is shown in Fig. 1. Amlodipine inhibited CYP3A4 activity in a concentration-dependent manner. Amlodipine inhibited CYP3A4 activity with an IC$_{50}$ value of 9.1 µM.

Rhodamine-123 retention assay

The effect of amlodipine on the cellular accumulation of rhodamine-123 in MCF-7 and MCF-7/ADR cells is shown in Fig. 2. Accumulation of rhodamine-123 was reduced in MCF-7/ADR cells overexpressing P-gp compared to that in MCF-7 cells lacking P-gp. The rel-
Effects of Amlodipine on the pharmacokinetics of Repaglinide

ative cellular uptake of rhodamine-123 was comparable at the concentration range of 1-10 µM amlodipine. This result suggests that amlodipine could not inhibit P-gp activity.

Effect of amlodipine on the pharmacokinetics of oral repaglinide

Mean arterial plasma concentration-time profiles of repaglinide following oral administration of repaglinide (0.5 mg/kg) to rats without or with amlodipine (0.1 and 0.4 mg/kg) are shown in Fig. 3; the corresponding pharmacokinetic parameters are shown in Table 1. Amlodipine significantly altered the pharmacokinetic parameters of repaglinide. Compared to the control group (given oral repaglinide alone), amlodipine significantly increased the area under the plasma concentration-time curve (AUC₀–∞, p < 0.05 at 0.4 mg/kg) and the peak plasma concentration (C_max, p < 0.05 at 0.4 mg/kg) of repaglinide by 40.2% and 22.2%, respectively. Amlodipine increased the absolute bioavailability (AB) of repaglinide by 41% (0.4 mg/kg, p<0.05) compared to the oral control group, and the relative bioavailability (RB) of repaglinide by 1.18- to 1.40-fold. There were no significant differences in the time to reach peak plasma concentration (T_max) and terminal half-life (t_1/2) of repaglinide between the presence and absence of amlodipine.

Effect of amlodipine on the pharmacokinetics of intravenous repaglinide

Mean plasma concentration-time profiles of repaglinide after the intravenous administration of repaglinide (0.2 mg/kg) to rats without or with amlodipine (0.1 and 0.4 mg/kg) are shown in Fig. 2; the corresponding pharmacokinetic parameters are shown in Table 1. Amlodipine significantly altered the pharmacokinetic parameters of repaglinide. Compared to the control group (given intravenous repaglinide alone), amlodipine significantly increased the area under the plasma concentration-time curve (AUC₀–∞, p < 0.05 at 0.4 mg/kg) and the peak plasma concentration (C_max, p < 0.05 at 0.4 mg/kg) of repaglinide by 40.2% and 22.2%, respectively. Amlodipine increased the absolute bioavailability (AB) of repaglinide by 41% (0.4 mg/kg, p<0.05) compared to the intravenous control group, and the relative bioavailability (RB) of repaglinide by 1.18- to 1.40-fold. There were no significant differences in the time to reach peak plasma concentration (T_max) and terminal half-life (t_1/2) of repaglinide between the presence and absence of amlodipine.

0.4 mg/kg) are shown in Fig. 4, while the correlated pharmacokinetic parameters are shown in Table 2. The AUC of repaglinide was increased, but was not statistically significant compared to that in the control. The $t_{1/2}$ of repaglinide was also prolonged, but this increase was not significant. The pharmacokinetics of intravenous repaglinide was not affected by the concurrent use of amlodipine in contrast to those of oral repaglinide. Accordingly, the enhanced oral bioavailability in the presence of amlodipine, while there was no significant change in the pharmacokinetics of intravenous repaglinide, may be mainly due to inhibition of the CYP3A-mediated metabolism of repaglinide in the small intestine and/or in the liver by amlodipine rather than renal elimination of repaglinide.

**DISCUSSION**

Type 2 diabetes mellitus is a common health problem associated with cardiovascular disease, with an increasing incidence worldwide. In clinical, repaglinide and amlodipine could be prescribed for prevention or treatment of cardiovascular disease as complications of diabetes. Considering that the drugs used in combination therapy often share the same metabolic pathways or cellular transport pathways, there is a high potential for pharmacokinetic drug interactions between repaglinide and amlodipine. Consequently, this study was to investigate the effect of amlodipine on CYP3A4 activity, P-gp activity and the pharmacokinetics of repaglinide after oral and intravenous administration in rats.

*In vitro* and *in vivo* studies have assessed the potential for repaglinide to interact with other drugs in clinical use. One of the principal cytochrome P450 isoforms involved in repaglinide metabolism in human liver microsomes is CYP3A4. CYP3A4 is the most abundant isoform of cytochrome P450 in the human liver and is responsible for the metabolism of many different drugs. Levels of CYP3A4 vary substantially between individuals; these variations may be related to induction of the isoform by various drugs and may partially account for the observed inter-individual variations in repaglinide metabolism. As CYP3A9 expressed in rat corresponds to the ortholog of CYP3A4 in human, and rat CYP3A2 is similar to human CYP3A4. Human 3A4 and rat 3A1 have 73% of protein homology. Rats were selected as an animal model in this study to evaluate the potential pharmacokinetic interactions mediated by CYP3A4, although there should be some difference in enzyme activity between rat and human.

Effects of Amlodipine on the pharmacokinetics of Repaglinide 

Considering that repaglinide is a substrate of both CYP3A4 and P-gp, the effects of amlodipine on the CYP3A4 activity and the cell-based P-gp activity were evaluated.

CYPs enzymes make a considerable contribution to the first-pass metabolism and oral bioavailability of many drugs. Moreover, induction or inhibition of CYPs may be responsible for significant drug and drug interactions. Modulators of P-gp can enhance or limit the permeability of a number of therapeutic agents that are considered substrates of this efflux pump protein. Therefore amlodipine, an inhibitor against both CYP3A4, should have a great impact on the bioavailability of many drugs where CYP3A4 metabolism, is the major barrier to the systemic bioavailability of its substrates.

As shown in Fig. 1, amlodipine inhibited CYP3A4 activity with an IC\textsubscript{50} value of 9.1 µM. However, the relative cellular uptake of rhodamine-123 was comparable (Fig. 2). It suggested that amlodipine could not inhibit P-gp activity. The inhibitory effect of amlodipine against CYP3A-mediated metabolism was confirmed by the employment of recombinant CYP enzymes. Poor solubility and first-pass metabolism in the liver and epithelial cells of the small intestine result in low bioavailability of repaglinide (56%). CYP3A4 inhibitors might alter the bioavailability and pharmacokinetics of repaglinide.

In this study, amlodipine significantly increased AUC\textsubscript{0–\infty} of repaglinide by 40.2% and the RB of repaglinide by 1.18- to 1.40-fold. Because amlodipine considerably increased \( C_{\text{max}} \) of repaglinide, it seems that amlodipine inhibited the CYP3A4-mediated biotransformation of repaglinide mainly during first-pass metabolism. CYP3A4 is present in considerable quantities in the small-intestine mucosa, and the intestine CYP3A4 has been shown to play a major role in drug interactions with CYP3A4 inhibitors. These results are consistent with a report by Niemi et al. showing that clarithromycin, a CYP3A4 inhibitor, significantly increased the AUC\textsubscript{0–\infty} and \( C_{\text{max}} \) of repaglinide. Niemi et al. reported that gemfibrozil significantly increased the AUC\textsubscript{0–\infty} of repaglinide 8.1-fold. This result is also consistent with our study.

After intravenous administration of repaglinide with amlodipine, the AUC\textsubscript{0–\infty} of repaglinide was increased, but was not significant. The CL\textsubscript{f} values of repaglinide tend to decrease, but was not statistic significant. This suggests that the effects of intravenous amlodipine on the inhibition of hepatic metabolism of repaglinide via CYP3A4 were almost negligible. In contrast to those of oral repaglinide, the pharmacokinetics of intravenous repaglinide was not affected by the concurrent use of amlodipine. Accordingly, while there was no significant change in the pharmacokinetics of intravenous repaglinide, the enhanced oral bioavailability may be mainly due to inhibition of the CYP3A-mediated metabolism of repaglinide in the small intestine and/or in the liver by amlodipine rather than P-gp and/or renal elimination of repaglinide. Although there are potential adverse effects, this interaction may provide a therapeutic benefit whereby it enhances bioavailability, allowing a reduction in the dose administered. Since the present study has raised the awareness of potential drug interactions by concomitant use of amlodipine with repaglinide, the clinical significance of this finding needs to be further evaluated in clinical studies.

**CONCLUSION**

In conclusion, amlodipine significantly enhanced the oral bioavailability of repaglinide. The enhanced bioavailability of repaglinide may be attributable to the inhibition of the CYP3A4-mediated metabolism in the small intestine and/or in the liver rather than both to inhibition of P-gp in the small intestine and to reduction of renal elimination of repaglinide by amlodipine. The increase in the oral bioavailability of repaglinide should be taken into consideration of potential drug interactions when coadministering repaglinide and amlodipine.
